What is Java? (Popular Perception)

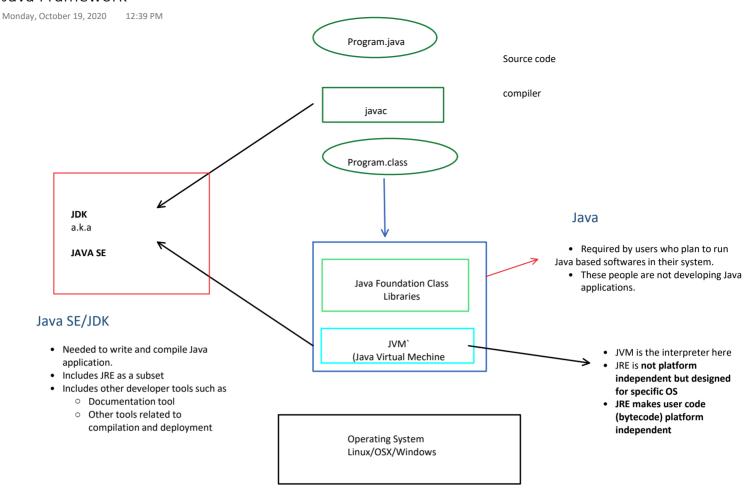

Monday, October 19, 2020 11:36 AM

Since the release of Android Studio 3.0 in October 2017, Kotlin is included as an alternative to the standard Java compiler. The Android Kotlin compiler lets the user In the world of computation Java refers to two related but distinct terms 1. Java is a Programming language 2. Java is an execution Platoform/Enivironment Different language choose between targeting Java 6 or Java 8 compatible bytecode. Kotlin has been Google's preferred language for Android app development since 7 May 2019. Kotlin Object oriented Platform independent Multi-threads Program This is a different programming language which produces a byte code just like Java compiler do. Javac (java compiler) Kotlin compiler Although it is NOT written in Java, It will still work on Java Platform Platform independent Program.class Android and IOS doesn't support Java platform and they are not considered Dalvik compiler Java systems. Byte code Write once run JVM For OSX Java (JVM for windows) Anywhere* * where JVM is present Program.apk Anroid doesn't have JVM Can't execute A .class file have JVM Can't execute A .class file Dalvik Virtual Machine OSX (Macbook) Android OS

Dalvik Virtual machine is an customized non-standard Runtime which is different from JVM and the two are **NOT** interoperable

Java Framework

Java Environments based on Use cases

Monday, October 19, 2020 12:49 PM

- Java desktop application user

 Needs to install JRE

 The product will include additional library

Java Desktop API

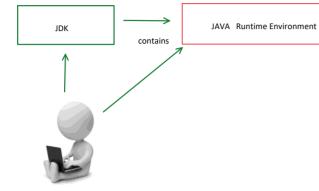

Server needs to install

Java Web API

Webapp user

Contains JVM

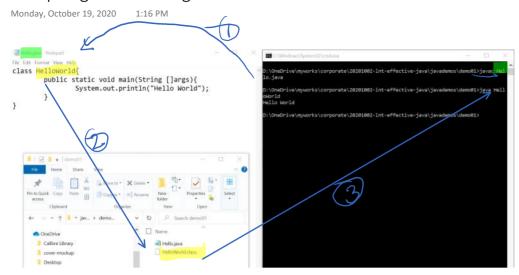

Foundation class libraries

Just needs standard browser.

- Doesn't require to install anything related to java NO JRE
 - NO other software

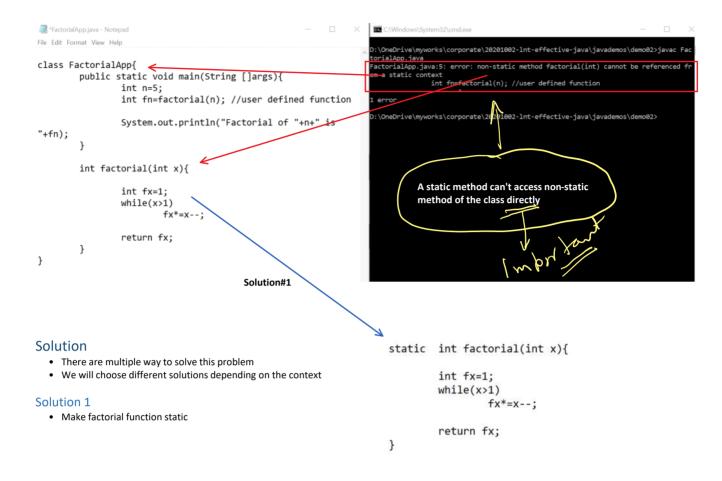

Compiling and Running Java code

- You compile a source file
 javac Hello.java
- 1. The byte code name is same as that of Class present in source code and not same as the .java file name
- 2. You run the byte code using java command
- c:> java HelloWorld

Static context

Monday, October 19, 2020 1:33 PM

More on static context

```
class FactorialApp{
    public static void main(String []args){
        int fn=Factorial.calculate(n);

        System.out.printin("Factorial of "+n+" is "+fn);
    }
}

class Factorial(
    int fn=Factorial.calculate(n);

    System.out.printin("Factorial of "+n+" is "+fn);
}

class Factorial{
    int calculate(int x){
        int fx=1;
        while(x>1)
        fx*=x--;
        return fx;
}

class Factorial fx;
}

class Factorial fix fx=1;
        while(x>1)
        fx*=x--;
        return fx;
}

class Factorial fx;
}
```

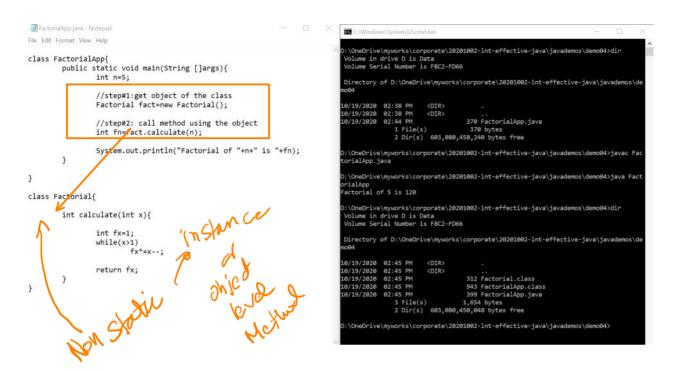

A Class name is a static context. You can call only static methods using Class reference and not nonstatic methods

Working with a non-static context

To work with a non-static method, we need an object of the class to

Working with a non-static context

To work with a non-static method, we need an object of the class to refer and use the method.

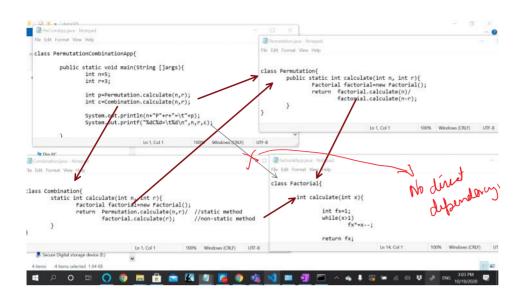

Multi Class Java Program

Monday, October 19, 2020 2:36 PM

```
FactorialApp.java - Notepad
                                                                                                         C:\Windows\System32\cmd.exe

```

Class Dependencies

Monday, October 19, 2020 3:03 PM

- Unlike c/c++ (or event javascript or python)
 You don't need any kind of include of classes before you can use.
 - An .class present in the current folder can be accessed directly.

How to compile a project with multiple files

Method #1 compile all files using * wildcard

c:> javac *.java

Method #2 compile the startup file — the one that contains main()

The steps would be as follows

- ${\bf 1.} \quad \text{It will try to compile PerComApp.java to create class PermutationCombinationApp.class}.$
- While compiling it needs to use Permutation class
- 2. Javac searches for a file Permutation.class
- It is not currently present
- 3. Javac searches for file Permutation.java.
- It compiles Permutation.java to create Permutation.class
 While compiling Permutation.class, it realizes it Needs Factorial.class
 - There is no Factorial.class present
- 5. Since there is not Factorial.class Present, it searches for Factorial.java
 - Factorial.java is also not present
 - Factorial class is a part of FactorialApp.java file. It is not housed in a file name of its own
 - At this stage it returns an error message

if I have both Combination.class and Combination.java file present, which of them will be used by javac?

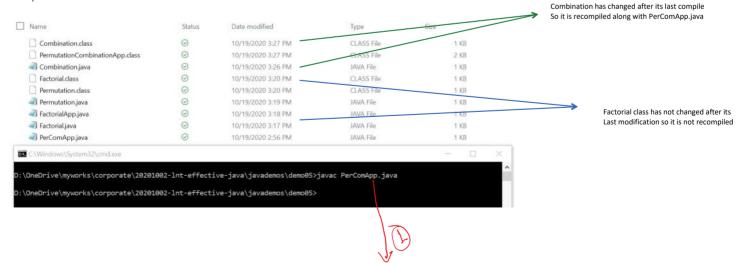

- If both files are present, then javac would compare their last modification data.
- If .class file is more recent than .java file, that means there has been no change in source code since last compilation, it would simply use the class file.
- If the class file is modified after last compilation, that means we must rebuild class file

 It would recompile the java file

Recommendation!

- We should create one class per java file
- A class should be housed in a java file of same name
- This will help Java compiler automatically compile your java file if required.

Compilation based on Modification

This file will always be compiled irrespective of its date as we are explicitly compiling

Organization Project files in multiple folders

Monday, October 19, 2020 3:32 PM

```
C:\Windows\System32\cmd exe
        PATH listing for volume
 olume serial number is F8C2-FD66
    FactorialApp.java
    PerComApp.java
              ConsoleWriter.java
              Combination.java
              Factorial.java
              Permutation.java
  :\OneDrive\myworks\corporate\20201002-lnt-effective-java\javademos\demo06>javac PerComApp.java
 PerComApp.java:8: error: cannot find symbol int p=Permutation.calculate(n,r);
 symbol: variable Combination
location: class PermutationCombinationApp
erComApp.java:11: error: cannot find symbol
  symbol: class ConsoleWriter
location: class PermutationCombinationApp
  erComApp.java:11: error: cannot find symbol
ConsoleWriter writer=new ConsoleWriter();
  symbol: class ConsoleWriter
```

How do I locate .java/.class files

1. CLASSPATH

- We can specify an environment variable called CLASSPATH listing all the folders where javac/java should search for .java/.class files
- Folders should be separted using path separator character that varies from one os to another
 - Windows using semicolon
 - Linux/osx uses colon

Our class path should look like

```
c:>set classpath=.\lib\console;.\lib\maths;.
Current directory
```

Java compiler by default doesn't know where to search for the java/class files if it is not present int current folder.

It doesn't search entire file system for those files

Note

- We have mentioned 3 path here
 - o .\lib\console
 - .\lib\maths
 - o . (current directory)
- We can't specify just lib
 - o We must include right sub directory
- If you are having a classpath, then java/javac doesn't search current directory by default.
 - You must include current directory if you have files in current directory

```
Volume serial number is F8C2-FD66
D:
FactorialApp.class
FactorialApp.java
PerComApp.java
PermutationCombinationApp.class

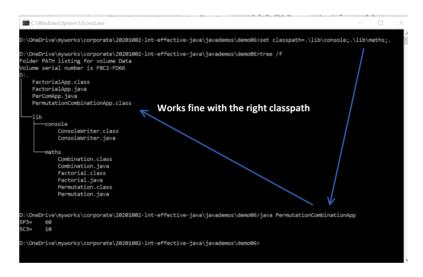

Console
ConsoleWriter.class
ConsoleWriter.java

maths

Combination.java
Factorial.java
Permutation.class
Permutation.class
Combination.java
Factorial.java
Permutation.class
Permutation.class
Permutation.class
Permutation.class
Permutation.class
Permutation.class
Permutation.java

D:\OneDrive\myworks\corporate\20201002-Int-effective-java\javademos\demo06>java PermutationCombinationApp
Caused by: java.lang.ClassNotFoundException: PermutationCombinationApp
D:\OneDrive\myworks\corporate\20201002-Int-effective-java\javademos\demo06>
```

Works correctly with the Right Path Set

Note About class path

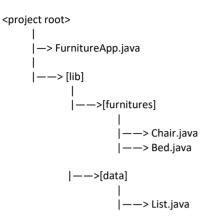

- Any classpath set at the terminal or the command window is good for current session only and is lost once you close the window.
- Classpath or any environment variable set on a terminal/command window is not available to other terminal or the command window.
- If you need a classpath everyday then you must store it in system environment variables
 - A good place to store classpath for common libraries.

Assignment01

Monday, October 19, 2020

4:01 PM

Create A Project called Furniture App with following file structure

FurnitureApp should

- 1. Craete a list of Furnitures
- 2. Add Chair and Bed to this list

Write necessary code to compile and run the program

What is a Table?

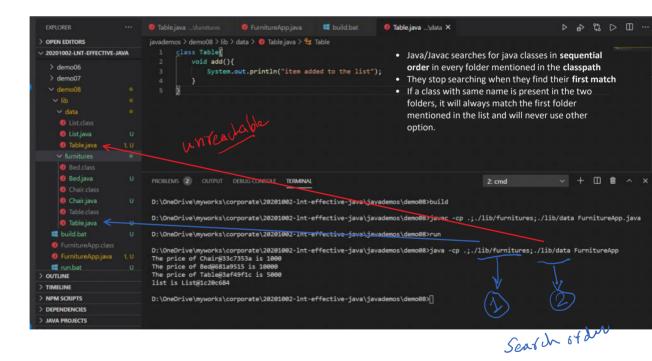

That?		
Product	Rate	Stock
Chair	1000	12
Table	5000	7
Bed	20000	4

- In real world a word can have different meanings. Same word (like Table) can represent multiple different and unrelated elements.
- Often in a single project we may need to use one or more such objects
 - Example:
 - A Furntiure Shop sells Table (Furnitures)
 - The maintain their stock details in a Table (Data)

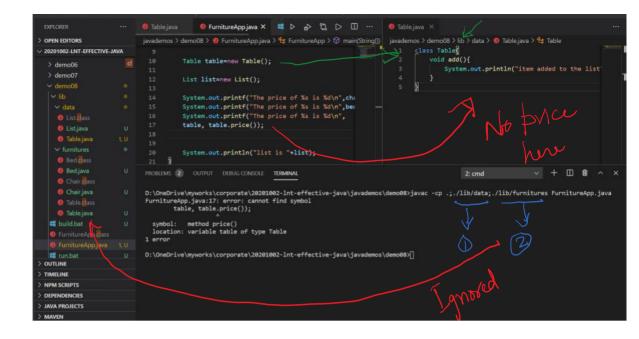

How do I represent Multiple Objects with same name in same application

Why Multiple Folder Design Doesn't work?

If we change the order in classpath, it will get a different Table. But we can't get Both Tables to work in single Application

How to make it work?

- Create classes with different Names
 - FurntiureTable
 - DataTable
- This can avoid name conflicts
- Why this is not a great idea
 - o We may not always be in a position to find a good prefix
 - o Sometimes conflict may be between
 - Your Data Table
 - My Data Table
 - \circ $\;$ Two different developers may be developing a class for same Purpose
 - Prefixing won't be useful here!

Java Package

Tuesday, October 20, 2020 10:21 AM

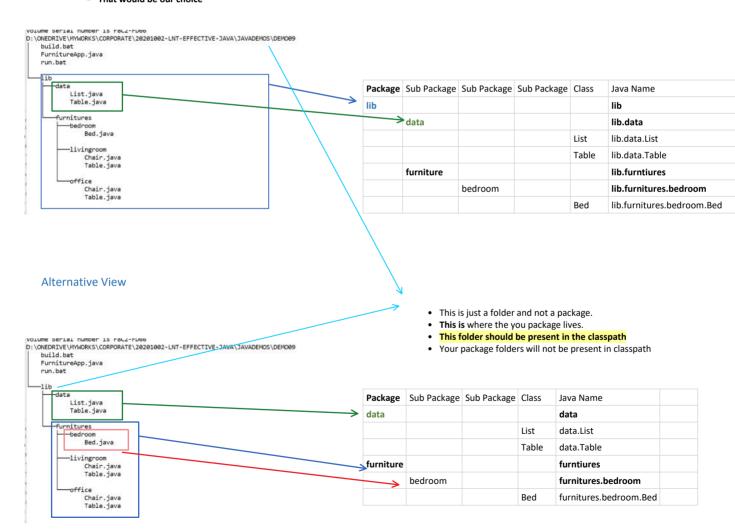

- A java package is a logical grouping for your Java classes and packages
- A Package can contain
 - o Java files
 - Class files
 - o Other Resource (configurations)
 - Sub Packages
- . A package is physically mapped to a folder on the disk.
- For every package you will have folder

Package is not a folder

- Package resides in a folder.
 - o If we have a package xyz it would be mapped to a folder xyz
- The key difference between a package and a folder
 - Folder is an OS concept and Java doesn't know about the folder
 - i. You reach the folders using OS level environment variable like classpath
 - ii. Java program internally knows nothing about a folder
 - Package is a java concept mapped to folders.
 - It is a java programming element and using in Java Program
 - · We can designate our selected folder as package
 - That would be our choice

Note!

 A class which is not part of any specific package is still a part of a global package

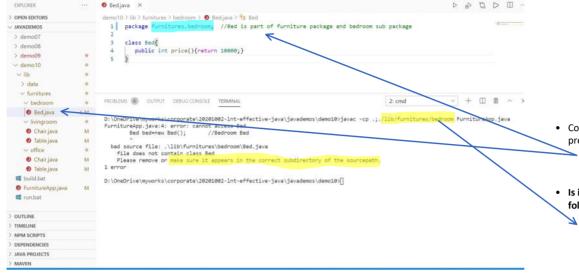

How do you mark your package?

• We mark our package and sub package by giving **package** statement on the top of class

- o package statement if present must be the first statement in a file.
- o There can be only one package statement per file
- o Package must include entire package sub package hierarchy
- o If not package is specified it is assumed to be part of a global un-named package
- o .class file must be present in folder mentioned as per package hierarchy
- Root of the package should be present in CLASSPATH FurnitureApp.java Bed.java Ust.java X List.java > {} data Bed.java > 😤 Bed package /we decided that my package starts 1 1 packag //Bed is part of fur 2 2 class Bed{ 3 3 class List{ void add(){ public int price(){return 10000;} 5 System.out.println("item added to the list' 6

Using Package

Tuesday, October 20, 2020 11:35 AM

Compiler is expecting **Bed** to be present in a folder

furnitures/bedroom

Is it not already present in the right folder?

- ✓ No.
 - Because we are searching for this folder by going inside this folder.
 - Remember this path is part of classpath
 - Javac goes into the folder and searches those folder inside

IMPORTANT!

 The error is because package name is mentioned in

CLASSPATH

- You should never mention package itself in classpath
- You should mention the Parent folder for package in class path

Referring a class defined inside the package

- Once you have created a class Bed inside a package furnitures.bedroom,
 - o you can't access the class simply as **Bed**
 - There is not Bed present in global package
 - You have to access the class Bed using its package qualified name that is furnitures.bedroom.Bed

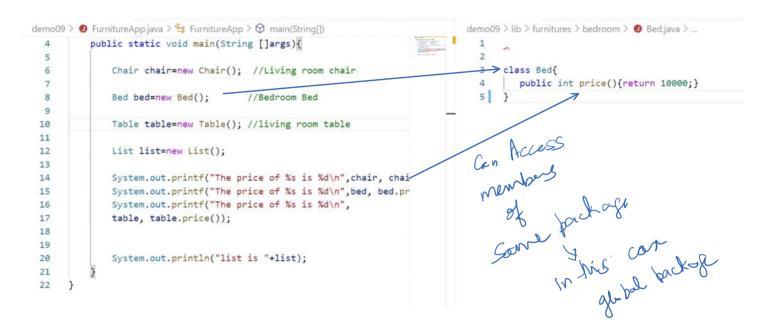

- Can't access Bed without package qualification
- Here is the right way to use it

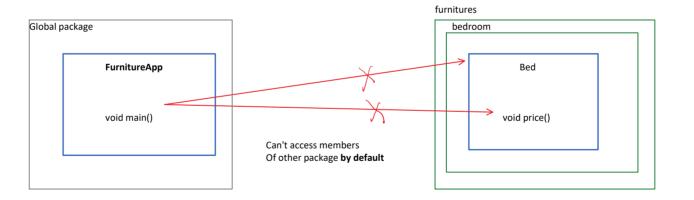

Package and Scopes

Tuesday, October 20, 2020 11:56 AM

- By default, all elements inside a package (class, class fields, class methods) have a package scope.
- They are accessible by members of the same package but not outside the package
- When we write program without package, all classes are part of same global package and can access each other and their method without any problem

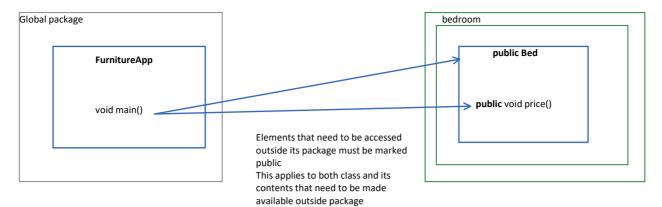

When Using Package

Scope: public

When Using Package

furnitures

Important!

- We don't need all classes and class contents to be directly accessible from outside
- Example
 - o You car needs an engine
 - o Engine need to be directly accessed by the driver
 - o You access car using few public elements like
 - Steering
 - Gear
 - Clutch, Break, Acclereator Paddles
 - This public components internally use other components which are not directly used by drivers
- We can make
 - public class Steering{}
 - class Engine {} <— no scope is package scope

Assignment02

Tuesday, October 20, 2020 12:11 PM

Complete the furniture shop app by

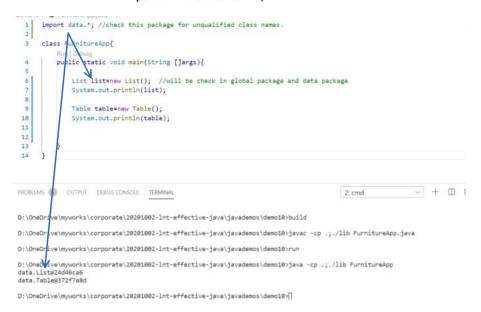

- Adding the right packages
- Use all the classes from all the package in the main function
- Update build and run script
- Build your project
- Run your project
- Take a screen shot of running code
- Update everything Assignment02 folder

Package Import

Tuesday, October 20, 2020 12:54 PM

import packagename.*; or import an entire package

- It imports all the packages from the given package
- When you use an unqualified name it searches for this name in
 - o Global package
 - Imported package
- NOTE
 - o import packagename.* imports only current package and its classes
 - It doesn't import subpackages
 - import furnitures.* will not import subpackages or their classes like furnitures.bedroom.bed
 - You must import
 - □ import furnitures.bedroom.*;

Problem with the wildcard (*) import

Recommendation

Avoid wildcard imports

Single class Import (Selective Import)

- Selecting import imports a single class at a time
- They can override wild card import
- If single class import is specified it will be preferred to resolve conflicts coming from wild card import

```
● FurnitureApp.java ×
demo10 > ① FurnitureApp.java >
      import data.*; //check this package for unqualified class names.
       import furnitures.bedroom.*;
      import furnitures.livingroom.*;
       //avoiding wild card conflicts
                                                                                                overribed round
fully gratified round
fully gratified round
conflict ones
       import data.Table; //unqualified Table means Data.Table
  6
      class FurnitureApp{
           public static void main(String []args){
               List list=new List(); //will be check in global package and data package
 10
 11
               System.out.println(list);
 12
               Table table=new Table(): //data.Table
 13
 14
               System.out.println(table);
 15
 16
               Bed bed=new Bed();
                                        //no conflict
 17
               System.out.println(bed);
 18
               Chair chair=new Chair(); //furnitures.livingroom.Chair
 20
               System.out.println(chair);
 21
 22
               //How do I resolve furnitures.livingroom.Table
 23
               //by using fully qualified paths
               furnitures.livingroom.Table table2=new furnitures.livingroom.Table();
 24
 25
               System.out.println(table2);
 26
 27
               //same goes for office furnitures
 28
```

A Good Package Name?

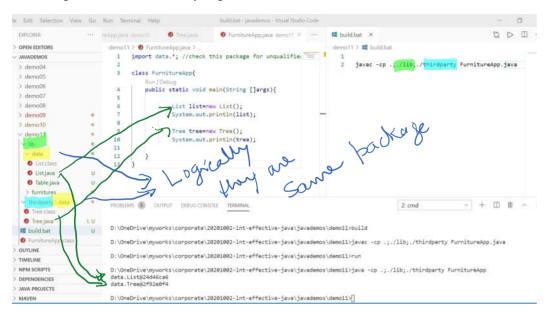

Tuesday, October 20, 2020 1:11 PM

A Package Name Avoid class name conflict. What if Package Name Conflict?

- What if two developer choose to create same package data
- Is it likely?
 - o YES.

How to resolve package name conflicts?

· Package name doesn't conflict. They merge!

- Package with same in different physical paths are considered to be same package.
- There names don't conflict.
- The content of two packages are treated as part of same package

What is the probability that two different developers would end up creating a package called **data** and have a class inside this package called **List?**

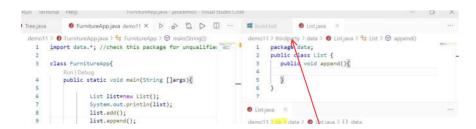

- It is very likely.
- List is a popular element in programming (and real world)
- · A List is most likely be present in a package which would be called
 - data
 - o collection
 - $\circ \quad \text{Datastructure} \\$
- Because these names are few, it is highly likely that many developers would use the same packages to house same classes

What happens if two different package with same name exists in the class path

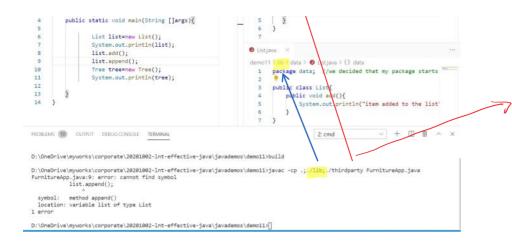

• They merge as one package

What happens if these two different package has class with same name?

- The class name conflicts
- There is no resolution to this problem
 - o Java has no solution to this problem

Due to classnath order

- Due to classpath order, javac/java never sees the second class with conflicting name
- Since Java does see it and doesn't complain for it, there is no way to resolve it

Conventional Solution

- Make sure your package name is unique
- Generally we never create a one level package (eg. Data)
- We create nested package
- The root package should be an identity/branding package
 - o E.g.
 - vivek.data <— data belongs to vivek
 - santosh.data <— data belongs to santosh

Recommendations

- Make sure your identity pacakge (root package) is unique
- One way to ensure is to use copyrighted names as identity
 - Your name is not copyrighted
- Company Name is copyrighted
- We generally use our domain name as package name (in reverse order)
 - o Example
 - in.conceptarchitect.data
 - com.ltts.projedt19.data
 - com.ltts.commons.data
 - in.conceptarchitect.furnitures.office
- A package may include project name or department name as sub package in case or large organization

Problem!

- What is the probability that two vivek will create a package called data and have a class inside called List?
 - High Probality
 - o Human names are quite common
 - Not a great choice for avoiding name conflict

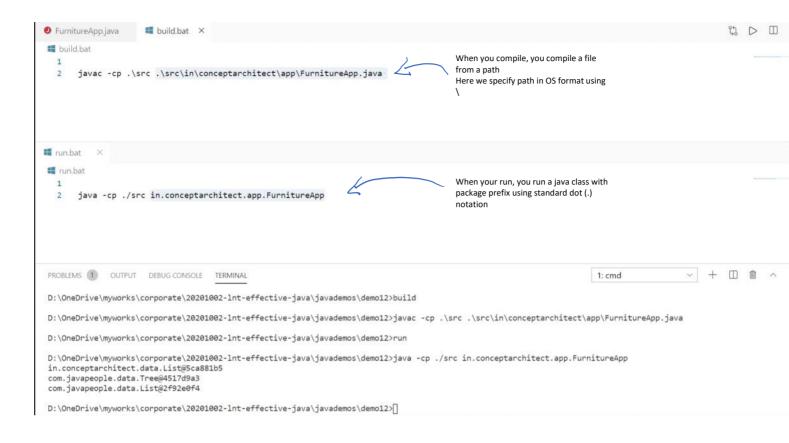

Assignment03

Tuesday, October 20, 2020 1:40 PM

- Start with demo11
- Create your brand:
 - o You may use
 - in.surname.name as your package
- Add identity spaces for lib packages as your brand package
- Add identity package com.javapeople as identity to the thirdparty library
- Use all the classes created so far
- Create build path and screenshots.

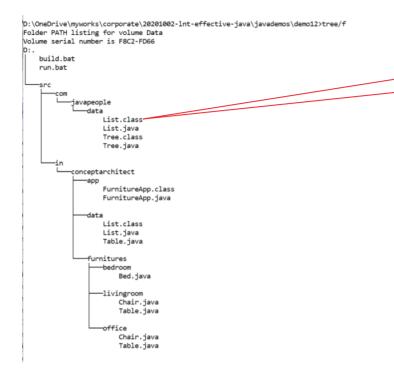

Building Project with nested classes

Tuesday, October 20, 2020 3:19 PM

Organizing your code for Deployment

Tuesday, October 20, 2020 3:21 PM

- · Source file and .class files are present in same folder
- Source file is generally not required to run the code
- You may not distribute or share your source code with client. You will give only .class file
- As a developer we keep deleting older version of class files.
- Keeping them separate would be great for application design.

Solution

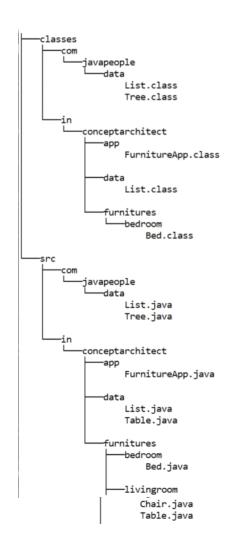

- 1. Keep all source files in **src** folder
- 2. Keep all class files in classes folder

Javac -d switch

- You can specify -d switch on javac to specify the folder in which you will store the class files
- In case of packages it will automatically create the package sub foders

- $2. \ \ \, \text{Only those classes required by the client is compiled} \\$
- ${\bf 3.} \ \ {\bf You} \ {\bf can} \ {\bf distribute} \ {\bf the} \ {\bf classes} \ {\bf folder} \ {\bf and} \ {\bf not} \ {\bf source} \ {\bf folder}$
- 4. You can delete all classes at once by deleting the classes folder

Chair.java Table.java — office Chair.java Table.java

Deployment

Tuesday, October 20, 2020 3:56 PM

A java program can with

- Class files in the disk
- Sub folders representing a package
- A batch file to run the command and class path

Problem

- In a typical java pragram, there would dozens of package (folders) and hundreds of class (files)
- To distribute the code to clients we need to copy all these files and folders
- Sharing so many files may require us to
 - Zip file files and send to client
 - o Ask client to unzip in the right folder
 - o Tell which java class contains main
 - o Tell them the command arugments

Solution

- · Create a jar file
- A jar file is like a zip file
- A java program can run from a jar file without needing to unpack it.
- You need to share a single jar file

1. Create a Jar File

Method 1 — Creating a simple jar

• This is the common method for creating a simple jar

```
c:> jar c v f app.jar .

c--> create a jar
v --> verbose - print whatever your are doing
f -> we will specify the name of output jar file (if not give the data is simply shown on console and no jar created)
. -> Jar files and subdirectories of current folder
```

Running code from a simple jar

```
c:> java -cp app.jar in.conceptarchitect.app.FurnitureApp
```

- We will specify the name of our jar as the CLASSPATH
- We will specify the full qualified name of the MainClass which contains the main function

A jar manifest

- A java jar file contains a manifest file ./META-INF/manifest.mf which contains meta informations about jar file
- This file is automatically added to ever jar and contains following sample information

//META-INF/manifest

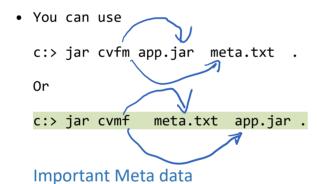

Manifest-Version: 1.0

Created-By: 15 (Oracle Corporation)

- To add more information to manifest we can
 - o Create a text file with additional information
 - o Specify the text file while creating the jar file using "m" option
 - o The content of your text file will be merged in standard manifest

c:> jar cvfm app.jar meta.txt

- Note app.jar is final jar file
- meta.txt contains additional data to be added to jar manifest
- The order in which you specify the two files depends on the order in which the options "m" and "f" is applied

Main-Class:

Specifies your main class within the jar

Class-Path:

• Specify additional class paths that you may need.

Running an application from a jar file that has Main-Class manifest entry

If your jar file has manifest entry you can use it to execute application simply by running

c:> java -jar app.jar

• This command automatically run class mentioned in Main-Class of manifest.

Method 3 -- inject Main Class Manifest only

- Incase you just want to specify MainClass to manifest and not other details such as verion, author etc you have an alternative jar creation syntax
- c:> jar cvef in.conceptarchitect.app.FurnitureApp app.jar .
 - "e" stands for entry point or Main-Class
 - You must specify the main class
 - This is automatically added in Manfiest.mf as Main-Class:
 - You don't need to create a meta.txt file just to specify Main-Class
 - o If you have to specify other information, you need to specify manifest

Assignment04

Tuesday, October 20, 2020

5:22 PM

- Create a class to represent a Bank Account
- A Bank Account will have
 - Account number
 - o Name
 - Password
 - o Balance
 - Interest rate
- A bank account will support following operations
 - Create an account
 - Deposit money
 - Should fail if amount <=0
 - Withdraw money
 - Should fail if
 - □ Amount<=0
 - □ Amount>balance
 - □ Password supplied doesn't match
 - Credit interest (one month interest)
 - Formula: balance=balance*rate/1200
 - o Provide getters/setters e.g.
 - Account number can't change in future
 - •
- Write a main program to test bank account details (menu driven)

Coding Conventions

Wednesday, October 21, 2020 10:00 AM

- Conventions are not syntactical compulsions.
- Violating convention doesn't cause compile time or runtime error.
- They simply make your code harder to
 - o Read
 - Maintain
 - o Debug
- Conventions are followed throughout developer community
- When we violate conventions other developers find it difficult to follow my codes

1. Package naming

- Your package name should be all lower case letter
- Package Name should start with two top level brand identity in reverse order or your domain
 - Eg.com.javapeoplein.conceptarchitectectorg.apache
 - In your design you can assume a domain such as
 - □ in.you-name or org.your-company
- Your business name should be a package at the depth 3.
- Don't use unbranded package names
- · Don't use single layer brands
 - Instead of com.app use com.javadev.finance.app
- A package name groups a set of classes
 - Package name should represent the purpose of that grouping
 - □ com.javadev.finance.data.Table
 - □ com.javadev.finance.ui.Table
- You may use a super package com.javatraining

2. Class Naming

- · Your class name should follow Pascal Naming Convention
 - Class Name should begin with an upper case letter
 - □ Triangle
 - Factorial
 - If using More than one word in class name
 - ☐ Each word should begin with upper case letter
 - □ Example
 - ◆ RaceCar
 - ◆ LinkedList
 - ◆ SortedArray
 - Names should be
 - □ Meaningful

	 □ Avoid an abstract name for a concrete class □ Your name should tell what is the purpose of the class ■ Avoid □ Names with all upper case letters unless you have very good reason like your class represents and Accronym ♠ CID ♠ GUID □ DON'T USE snake case naming ♠ Name where multiple words are separated by underscore (_) 				
2	Method Names				
Your method name should follow Camel Naming Convention Should begin with an lower case letter.					
	 Should begin with an lower case letter calculate() 				
	□ show()				
	If using More than one word in class name				
	☐ Each word starting second should begin with upper case letter				
	□ Example				
	getBalance()				
	toString()				
	createSavingsAccount()				
	 Names should be 				
	MeaningfulAvoid an abstract name for a concrete class				
	☐ Your name should tell what is the purpose of the class				
	 Avoid 				
	☐ Names with all upper case letters unless you have very good reason like your class represents and				
	Accronym				
	• generateGUID()				
	□ DON'T USE snake case naming				
	 Name where multiple words are separated by underscore (_) 				
	 □ Sometimes to highlight an private operation the name may begin with an underscore ◆ Acceptable. But avoid if you can 				
4.	Field Names				
•	Your field name should follow Camel Naming Convention				
	Should begin with an lower case letter				
	□ balance				
	□ amount				
 If using More than one word in class name 					
	 Each word starting second should begin with upper case letter 				
	□ Example				
	• intrestRate				
	Names should be Moaningful				
	☐ Meaningful☐ Avoid an abstract name for a concrete class				
	☐ Your name should tell what is the purpose of the class				
 Avoid Names with all upper case letters unless you are defining a constant 					
					◆ PI
	◆ MAX				
	□ DON'T USE snake case naming				

• Name where multiple words are separated by underscore (_)

□ Sometimes to highlight an private operation the name may begin with an underscore

What is Object Oriented Programming? (Popular Perception)

Wednesday, October 21, 2020 10:27 AM Why do I create an object for data and logic?
Why not create logic as functions and data as simple structure like in C language? Participants Feedbacks · Creating Objects that contains data and logic • Programming with class and objects • Real world objects like car etc. Why should I really program class and objects? Why do we call it object oriented programming and not class oriented programming or class and object oriented programming. Why do we need real world entities? o Because we program to solve a real world problem What is a Program? Where is object in (the definition) of Program? A set of instructions Why is there no reference to either object or class in definition of a Given to computer Program?

What is an Object Oriented Program?

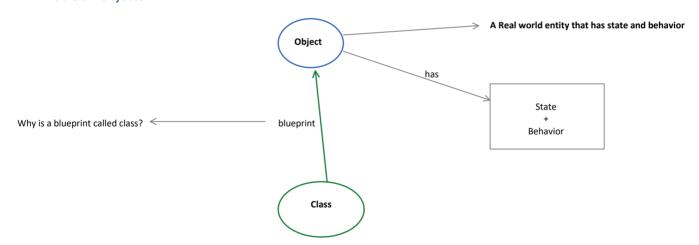

A **set of instructions** constructed by using **classes** and creating blueprint of that class called an **objects** to use the functionalities available in that

Three important words in the definition in decreasing order of priority

- 1. set of instruction
- 2. class
- 3. object

What is an Object?

For solving a problem.

Let's talk about a real world Object

Yamaha Alien —> A New Bike

- Colors
- Mileage
- cc
- Cost
- BHP
- AT/MT

What is the source of your knowledge about Bike?

• Because you use it

Dinasourous?

- Animal that existed years ago
- Lived in Jurassic park

What is the source of your knowledge about Dinasourous?

- Have you seen it?
 - Movies
 - Wikpedia

Object Oriented Design

Wednesday, October 21, 2020 10:57 AM

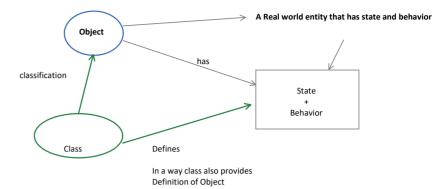

Domain The problem space

Object

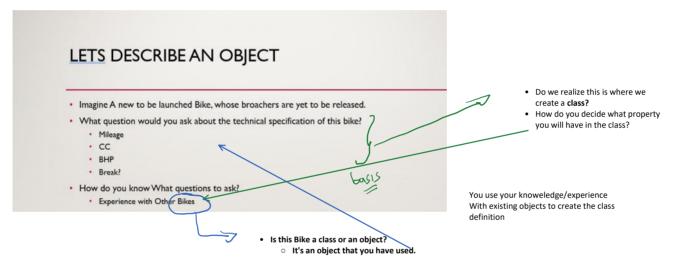

- Represents a Real World Physical Entity
- Object represents a Domain Entity
- · An Object can be
 - o Real World Physical --> Employee
 - o Real World Non Physical --> Department
 - o Non Real Physical --> Magic Wand
 - None Real World Non Physical --> Magic Wand
- · Has its State and Behavior
- Object is anything/everything that you can conceptualize

Class

- Class stands for Classfication
- Class is the basis of object classfication
- It defines parameters for such classfication
 - o State
 - behaviors

What comes First — Object or Class?

Why class comes first?

- Class is a language of feature of popular object oriented language like
 - o C++
 - o Java
 - o C#
- It is a semnatical compulsion but **not a real requirement for** Object Oriented Programming
 - o Remember we call is Object Oriented and not class Oriented
- There are Object Oriented langauges where Class doesn't even exist
 - Javascript
 - o New version has class, but that's optional

Creating An Object

Wednesday, October 21, 2020 12:48 PM

```
public class BankAccount {

int accountNumber;
String name;
String password;
double balance;
double interestRate;

void createAccount(int accNo, String name, String pass, double amount, double rate) {

accountNumber=accNo;

name=name;

password=pass;
balance=amount;
interestRate=rate;
}

}

BankAccountjava II
i package in.conceptarchitect.banking;

i package in.conceptarchitect.banking.app;
```

Solution

Option 1

• Don't use same name for parameter and the class fields (states)

Option 2 (PREFFERED)

- Use this keyword
 - o "this" is a special keyword in an object method that represents the current object
 - $\circ~$ So a "this.name" would always represent an object's property and not a method argument
 - You can always use "this" with any class field or method
 - We generally use it only to distinguish between method arugment and properties.

```
public class BankAccount {
    int accountNumber;
   String name;
String password;
    double balance;
    double interestRate;
                                                                                                                                       If there is a name conflict explicit
    public void createAccount(int accountNumber, String name, String pass
                                                                                      double amount, double rate) {
                                                                                                                                       use of this is required.
         this.name=name; //this.name is class field, name is argument
        this.password=password;
                           nt; //this is not required as balance has no conflict
                              //this is not required
                                                                                                                                       When there is no name conflict
                                                                                                                                         • this is optional and implicit.
                                                                                                                                          • Even when you don't write
    public void show() {
        System out println("Account Number\t"+this accountNumber\://this
                                                                                                                                            this. vou mean this as
```

What will this code do?

name=name;

- Whenever you have two different names in a given context a local (near) one is preferred over far one.
- This this case name refers to parameter that is passed which is closer to function that the class members.
- Here it would end up as a self assignment of function parameter.
 - o The code has No effect.

Value Type Vs Reference

Wednesday, October 21, 2020 1:13 PM

In Java Script a variable can be of two types

Value Types

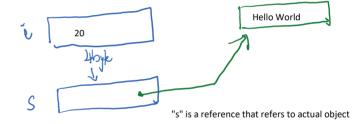

- A primitive data type is called value types.
- They are stored directly in the variable memory
- These include built-in data types such as
 - o int
 - o float
 - o double
 - o char
 - o byte
 - o Boolean

Reference Type

- It represents all complex data type which are created as class
- This also includes all user defined data types
- Variable stores the reference (address) of the actual object that would store value

Example 1 -- int is value type, String is reference type

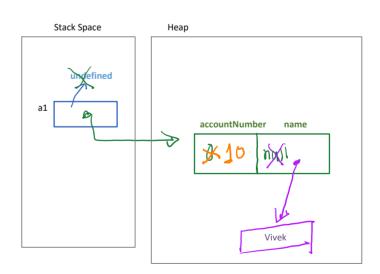

```
public static void main(String [] args){
   int i=20;
   String s="Hello World";
}
```

Example 2 — User defined Object

```
class BankAccount{
    int accountNumber;
    String name;
}

void main(){
    BankAccount a1; //draw memory model here
    a1= new BankAccount(); //draw memory model here
    a1.accountNumber=10; //draw memory model here
    a1.name="Vivek"; //draw memory model here
}
```

Assignment 5 -- Draw the Memory Snapshot for Following code

```
Wednesday, October 21, 2020 1:23 PM

class BankAccount{
    int accountNumber;
    String name;
}

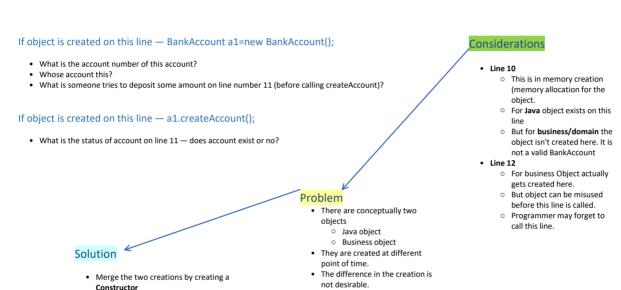

void main(){
    BankAccount a1; //draw memory snapshot 1
    a1= new BankAccount(); //draw memory model snapshot2
    a1.accountNumber=10; //draw memory snapshot 3
    a1.name="Vivek"; //draw memory snapshot 4
}
```

- You can create a single diagram and use 4 different color to define the 4 stage of memory allocation
- You may create 5 different diagrams

When is Object Created?

Wednesday, October 21, 2020 1:13 PM

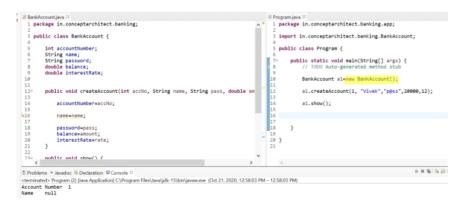

Constructor

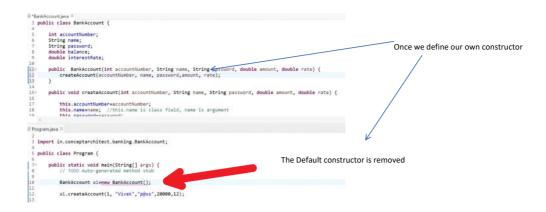

- A special class method
- Responsible for Object creation and initialization.
- Same name as that of class
- $\bullet \quad \hbox{No Return type} \hbox{not even void}.$
- Every class always has a constructor
 - If you don't create your own you get a default 0 argument nothing doing constructor
 - This constructor is removed once you provide your own constructor

Working With Default Constructor

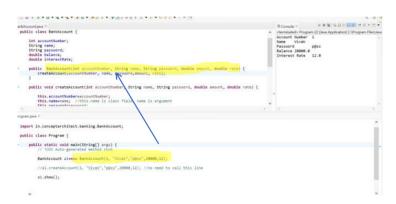

- Call to default constructor of BankAccount which is provided automatically by Java
- Note we haven't created our constructor.

Default Constructor is removed if we provide our own constructor

Right way to call the constructor

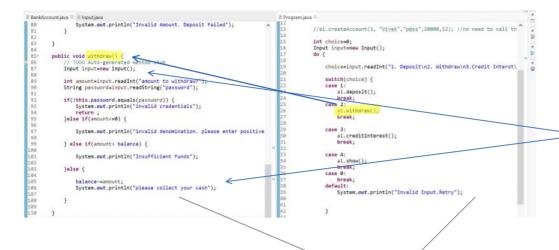

Constructor vs createAccount

- What to use?
- If we see our code, my constructor is calling createAccount.
- Why should I create constructor if I already have a createAccount()

Constructor Advantages

- 1. Constructor merges Programming creation with domain creation
- 2. Both constructor and create logic are executed at the same time.
- 3. Constructor is called only once for an object at the beginning.
- 4. Problem with creator
 - a. You may forget to call the method
 - i. Object will be invalid till you call it
 - b. You may call create method more than once for the same object
 - i. This is not desirable.

 There is Zero Interaction between Client (Program.java) and Service (BankAccount.java)

Problems

- Client has no way to know if withdraw was successful or it failed?
- Who is responsible for interacting with User?

Real world Banking Scenario

1. How will a user withdraw the money from his account?

ATM

- o ATM
- Mobile App
- Web App (paying a bill is also withdrawing from account)

- 2. Where is BankAccount object stored?
 - a. Is BankAccount object stored in ATM memory?
 - i. No.
 - b. It is stored on the central Bank server on a remote location (Cloud)

BankAccount a1

BankServer

- 3. Where will Input and Print Statement Execute on ATM or on Server?
 - a. On Server

Problem

- User has no access to the server
- User can reach server to type the input
- User can't see anything typed on the server console

Solution

- Don't include I/O logic (Input or print) in Business layer object
- Don't have any print statement in any not designed to display out
- BankAccount object should have BankAccount Business Logic But not User Interaction Logic
- User Interaction Logic should be present in Presentation layer object such as an ATM machine
- ATM machine should interact with Business objects behind the scene.

Wednesday, October 21, 2020 3:59 PM

- 1. Add mechanism to get/set password from the BankAccount Object
- 2. Remove all the Input/Print from BankAccount object
- 3. Move all User Interaction to ATM Object main Function

How do I allow BankAccount Password accessed or Modified

```
package in.conceptarchitect.banking;
import in.conceptarchitect.utils.Input;

public class BankAccount {
    int accountNumber;
    String name;
    String password;
    double balance;
    static double interestRate;

public String getPassword() {
        return password;
    }

public void setPassword(String password) {
        this.password = password;
    }
}
```

- Anyone can call getPassword() and display it using System.out.println
- · Not safe
- What is password is salted
 - Generally passwords are stored in an encrypted format in the database so that no one can know the true phrase of your password, including the admins
- Anyone can change your password without knowing your existing password.
- This makes password useless.

How should you model the password access/change mechanism

```
public class BankAccount {

int accountNumber;

String name;
String password;
double balance;
static double interestRate;

//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password hashing just to demonstrated
//Its a dummy and non-secured logic for password ha
```

Don't give them password. You ask them a password and confirm if it is the correct password.

Before you change the password, authenticate user with current password and then change

Wednesday, October 21, 2020 4:00 PM

- Introduce ATM object to include User interaction logic
- ATM should take user Input and interact with BankAccount Object

Consider a BankAccount class

```
class BankAccount{
    int accountNumber;
    double balance;
    double rate;
}
```

What happens if I create 3 BankAccount Objects?

```
BankAccount a1=new BankAccount(1,1000,10);
BankAccount a2=new BankAccount(2,1000,10);
BankAccount a3=new BankAccount(3,5000,10);
```

If you have 10000 different BankAccount objects, is it probable that

- Some of them will have same balance?
 - o YES
 - o May be but a coincidence
 - Each object will have their own balance
- All of them will have same balance?
 - No
- One or more of them has same name?
 - VES
- Same name may just be a coincidence
- Same account number
- NEVERSame rate of interest?
 - o ALWAYS
 - o For same type of account you would get same interest

Problem!

• Why should I create 10000 copies of same value?

Static Field

- A field that is marked static is a shared field in the class.
- There will be a single copy of that field irrespective of number of objects have
- We call them class level member
- Non static fields are called instance members or object level members
- They are not initialized by constructor, rather by static block

Note!

 Use static to create those states which are common and shared for all object of a class

A special copy each non-static or instance

member is created per object call

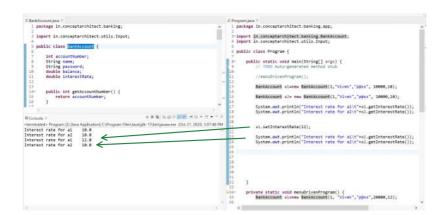

class BankAccount{
 int accountNumber;
 double balance;
 static double rate;
}

void main(){
 BankAccount a1=new BankAccount(1,1000,10);
 BankAccount a2=new BankAccount(2,1000,10);
 BankAccount a3=new BankAccount(3,5000,10);
}

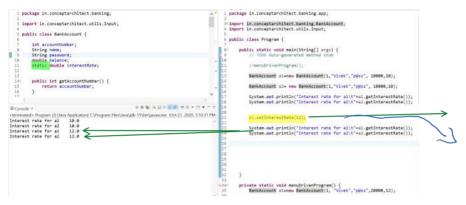

Each instance will access a common copy of the static field or class level field

Non-static interest Rate

- Each Object maintains its own copy of the object state.
- Change is one doesn't change value for others.

Changing Value for one changes for everyone

What is this code doing?

 Changing the interest rate for a1 or for everyone?

Problem

- It appears to be changing the rate for only a1.
- Actually its changing for everyone

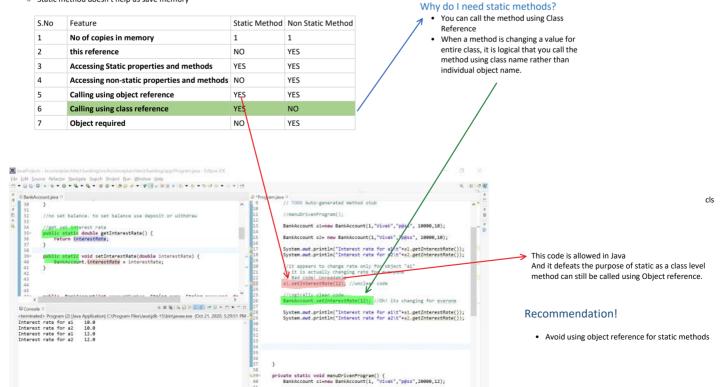

Remember

 If you cant understand what a code is doing, you can manage code

Static Methods

- Just like a fields, a method can also be static.
- A static method belongs to class.
- A static method doesn't contain "this" reference
- A static method can't access any **non-static** field or methods
- Both static and non-static method have only one copy present in memory.

Initializing Static Data

- . Don't initialize static data in constructor
 - o Constructor is called for every object
 - Static data is a single shared copy

Option 1

- Initialize by assigning a constant value wherever you declared static
- · This should be used if the initial value is const

```
class BankAccount{
    static double interestRate=10;
}
```

Option 2

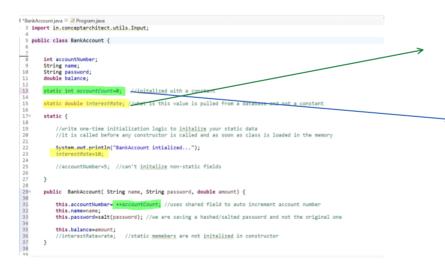

- We may need to get initial value from database or calculate them before use
- . In such cases we should use static initalization block

- Static block is invoked exactly once when the class is loaded
- It is done before any constructor or other methods of the class is called
- It can have logic for static initialization
- It can't access any non-static member of the class

Static Field Use Cases

- Share Common Data Between Objects
- Let object connect with each other based on that shared information

- Any change in Interest rate is done at one place
- Every object gets to use this value.
- They all share the interestRate like a constant for them
- Remember static is not constant. Its common or shared.
 - Can be used coordinating between object
 - We can have things like auto increment values which can help assign unique ids
 - We can also have a common block where one object can put some information and other object can pull the information from that common block.
- Here object constructor increments the common value (not-constant)
 The next constructor uses the incremented value to further increment it.

Static Method Usage

There are three popular usage of Static Methods

- 1. Define a generic function that is not connected any object
 - a. These are independent functions similar to a procedural programming
 - b. Examples:
 - i. public static void main(String []args)
 - ii. All Math formula present in Math class like Math.pow()
- 2. To access or modify static fields
 - a. Since you have static fields, they need to be modified or accessed event without object
 - b. To access or modify them it is better to create static methods
 - c. Example:

Why is main() static?

- main() is the first function that is called in your application.
- It is called by the JVM
- At this stage there is no one to create an object of the class
- JVM simply calls Program.main()
 - $\circ\quad$ It doesn't need to create an object of the Program class

Important!

- Static fields can be accessed even using non-static method
- The problem is
 - You need at least one object to call them
 - o The operation may look like applied on one object rather than on all object

2. To access or modify static fields

- a. Since you have static fields, they need to be modified or accessed event without object
- b. To access or modify them it is better to create static methods
- c. Example:

return true;
} else {
return false;

- BankAccount.setInterestRate()
- ii. BankAccount.getTotalAccounts()

3. To coordinate the interaction between multiple objects

a. What if I want to write a transferFunds method that transfers money from one account to another?

public static boolean transfer(BankAccount source, double amount, String password, BankAccount target) {

b. We can do it using BankAccount.transfer(a1,a2,amount,password);

πηρυπαιπ:

- Static fields can be accessed even using non-static method
- · The problem is
 - o You need at least one object to call them
 - o The operation may look like applied on one object rather than on all object

Concerns

• Here we are accessing non-static members in static block

Non-static method → o Non-static field

• But static methods can't access non-static members. Right? How is it working?

Remember!

- You can't access non-static member directly
- · Here we are not accessing those fields or methods
- We are calling the object and its methods
 - source.withdraw()
 - o target.balance+=amount
- I can't access withdraw() or balance directly
- Here since object is involved, its not a static context

Use Static or Not?

- · Do we agree
 - o interestRate is not owned by bank account object?
 - You own your name, password and balance
 - But you don't own or control interest rate
 - You certainly get the benefit of the interest rate
 - o Bank account object can't know the account count?

Concerns

- If an object doesn't own a property (that is why it is static), why is it present in the class?
 - A static element is not owned by object, it is owned by the class
- · Remember! A class is just the definition an object
 - o If it is not present in the object, why is it present in the

BankAccount doesn't know or own account count. Who owns it? Who controls interest rate?

Bank

}

- o A bank opens the accounts
- o A bank maintains a list opened accounts
- o A bank provides interest on the accounts
- o Interest rate and account count should be the property of a Bank object
- o Different bank can provide different rate of interests they choose

class BankAccount{ class Bank{ static int accountCount: static int accountCount; static double intrestRate; static double intrestRate; int acountNumber; double balance; static double getInterestRate(){return interestRate;} String name; static int getAccountCount(){ return accountCount;} String password; static double getInterestRate(){return interestRate;} static int getAccountCount(){ return accountCount;} public boolean deposit(double amount){ } public BankAccount(...){

Remember — Every static member of class X is actually part of some other object y of class Y

- . In real world there is no real use case of static
- · Static means no object or class level

• But classes are not real. They are just notions (abstract ideas)

Should I create 'Bank' class only because I want to keep my interest rate and account count there.

- No.You need Bank
 - You can't create an bank account object yourself
 - You need to go to some bank to open your account
 - You can't withdraw money from your account directly
 You need to go to bank to deposit/withdraw the money
 - o Bank mains a list of all the accounts that it has opened.

Banking Model 02

Thursday, October 22, 2020 10:09 AM

ATM

User

- 1. Allows you to interact with your BankAccount
- 2. Takes User Input
- 3. Sends request to Bank
- 4. Gets Response from Bank
- 5. Dispense cash if required.
- 6. Operations
- - a. Insert Your Card (Provide Account Number)
 - b. Main Menu
 - i. Deposit
- - 1) Enter Deposit Details ii. Withdraw
 - 1) Enter Amount
 - 2) Enter Pin
 - iii. Balance Info

- 1. Creates (opens) an account
- 2. Stores the account for future
- 3. Allows you to transact with your account
 - a. Deposit

Connect to

b. withdraw

BankAccount

- 1. Stores information about individual BankAccounts
- 2. Can be accessed only by the BankObject
- 3. Customer or ATM interacts with this object using BankObject

What is the role of main function here?

• It is to setup the ATM and BankAccount and Bank Object

```
class BankAccount{
class Bank{
int accountCount;
double intrestRate;
                                                                                            int acountNumber;
                                                                                           double balance;
BankAccount [] accounts;
                                                                                           String name;
double getInterestRate(){return interestRate;}
                                                                                           String password;
int getAccountCount(){ return accountCount;}
                                                                                           public BankAccount(...){
int openAccount(String name, String pass, int amount){
    int id=++accountCount;
    BankAccount newAccount=new BankAccount(id,name,pass,amount);
                                                                                            public boolean withdraw(double amount, String password){
    //store a list of bank account in bank object
}
boolean withdraw( int accountNumber, double amount, String password){
    BankAccount acc= getAccountById(accountNumber);
    return acc.withdraw(amount,password);
```

Thursday, October 22, 2020 10:47 AM

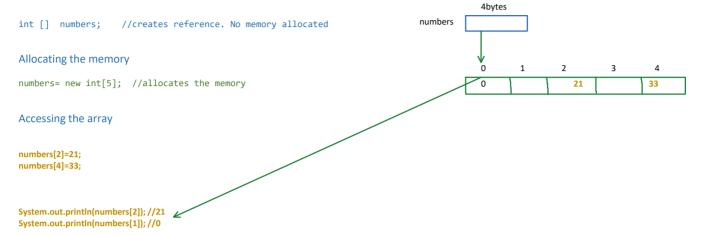

- In our current BankAccount user is specifying the account Number
- This may conflict between to different account as they may choose same account number
- Create a design to auto assign and auto incremented account number to every bank account that is created
- Constructor shouldn't take account number from the user.

Array

Thursday, October 22, 2020 12:53 PM

 An array is a continuous non-expanding list of values that can be accessed using zero based index

Creating an array

Trying to Access invalid Index throws exception

numbers[5]=29; //throws IndexOutOfBoundsException

numbers[-2]=29; //throws IndexOutOfBoundsException

System.out.println(numbers[21]); //throws IndexOutOfBoundsException

Initialzing Array with Fixed Values

int[] values={2,3,9,2,6}

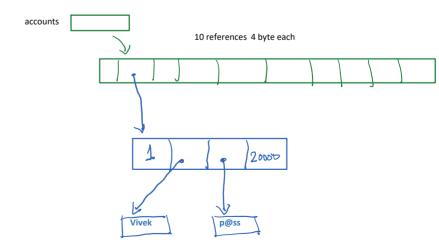

Array of Objects

- It uses the same style
- Creates an array of references
- Each reference refers to a different Object
- Objects will be stored in different memory

BankAccount accounts[] = new BankAccount[10];

Creating Actual Objects

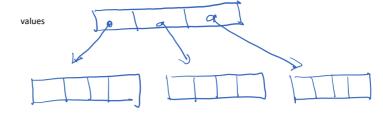

accounts[1]=new BankAccount(1,"Vivek","p@ss",20000);

Array of Array

- An Array can have another array as member
- This makes multi dimentional Array

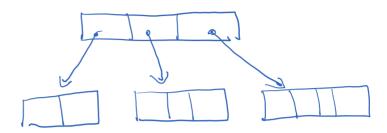

int [][] values= new int [3][4];

Non Rectangular array

int [] [] values= new int [3] []; //second is not given

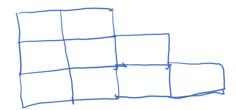

for (int i=0;i<values.length;i++)
 value[i]= new int[i+2];</pre>

Conceptual View

Multi-dimensional array is rarely used in Object Oriented Programming

We generally use array of objects rather than array or arrays

String

Thursday, October 22, 2020

- 1:14 PM
- Java Strings are immutable Objects
 - Once an object is created, it can't be modified in place
- Immutable design allows us to reuse the memory for a String object

Creating a string

String str="India";

String str2="India";

Since str2 is also the same immutable string, we will reuse it and not allocate a second memory

Important String methods

1	length()	Returns string length
	equals()	Compares if strings are equal (same)
	charAt()	Returns character at a 0 based index
	toUpperCase()	Converts String to upper case
	indexOf()	Index of another string into this string
	substr()	Returns a substring
	format()	Creates formatted strings with printf style syntax %s , %d etc

String is immutable

Any method that tries to change the string actually creates a new string and doesn't modify
existing one

String str="Hello World";
str.toUpperCase();

SHI THELLO WORLD

Note the changes are in a new memory. But no one refers this memory. So this change will not reflect any where and will be lost.

How to accept changes

String str="Hello World";
str=str.toUpperCase();

SHI HELLO WORLD

• Now str points to modified String

 It will be eventually garbage collected. 	

• The original string "Hello World" is no more referenced

Thursday, October 22, 2020 1:25 PM

- Create the necessary classes to Implment Banking Project as Per the Object Model 2
- Complete the code in Bank class and ATM class

Bank Account Types

Friday, October 23, 2020 9:43 AM

- In real world there are different type of BankAccounts
 - o SavingsAccount
 - CurrentAccount
 - OverdraftAccount
 - LoanAccount
 - o ...
- All these accounts have their own set of rules and facilities
- Here is a simple matrix of how these accounts may differ

Туре	Transactions Per Month	Max Withdraw Amoung	Credit Interest
Saving	50	balance-5000 If your balance is 20000 you can withdraw a max of 15000	Normal
Current	unlimited	Balance. If your balance is 20000, you can withdraw 20000	0
OverDraf t	20	Balance+odLimit You may withdraw more than you balance*	Normal

Od Limit For Overdraft Account

- An Overdraft Account provides an Overdraft facility
 - o It means if you required you can withdraw more than your actual balance
 - You will have to pay a charge for it
 - o How much you can withdraw is based on OdLimit
- An OdLimit is 10% of your historic max balance
- OdCharge is 1% of your Overdraft.

Example

- If altime highest balance in your account was 100000 (1 Lac)
 - o Your ODLimit -> 10% of 100000 = 10000
- Now if you current balance is 20000
 - You can withdraw upto 20000+10000=30000
- Suppose you want to withdraw 25000
 - o Your ovedraft will be 25000-20000=5000
 - The withdrawal will be permitted
 - You will have to pay an od charge
 - 1% of 5000=50
 - Your final balance will be : 20000 25000 50 = -5050

Friday, October 23, 2020 9:56 AM

- Create a different type of BankAccounts
- Implement the behaviors as per the provided matrix
 - Withdraw
 - Credit interest
- Add functionalities in Bank and ATM to
 - o openSavingsAccount
 - o openCurrentAccount
 - $\circ \hspace{0.1in} openOverdraftAccount \\$
